1. Active Learning

2. Anomaly Detection

Local Outlier Factor

One-class SVMs

Active Learning

- ▶ Remember: Acquiring labels is expensive
- ▶ Idea: Acquire labels only for the **'interesting'** samples
- ▶ Iterate:
 1. Machine selects a sample x
 2. Human expert assigns a label y to sample x
 3. Machine updates its model with (x, y)

```
1 model = init()
2 labeled_samples = {}
3 while ...:
4     x := select_sample(model, samples)
5     y := expert_label(x)
6     labeled_samples.add( (x,y) )
7     model := model.train(labeled_samples)
```

Remarks

- ▶ In general, this works with any **base classifier**.
- ▶ Only requirement: the base classifier can compute the **posterior** $P(Y = y|\mathbf{x})$
- ▶ Often, active learning targets two **different goals** (*“exploration vs. exploitation”*)
 - ▶ Detecting positive Samples (\rightarrow **satisfy the user**)
 - ▶ Exploration of feature space (\rightarrow **improve the classifier**)
- ▶ Challenge: Labels are usually **extremely scarce** (i.e., benchmarking our classifier is usually not possible)

Active Learning: Approaches

- ▶ Key Problem: Which are the **interesting samples** to select?
- ▶ There are different strategies towards **sample selection** (or **querying**)

Approaches

- ▶ **Uncertainty sampling**: Select the sample \mathbf{x} which the base classifier is most uncertain about:

$$\mathbf{x}^* = \arg \min_{\mathbf{x}} \left| P(Y = 1|\mathbf{x}) - 0.5 \right|$$

- ▶ **Relevance sampling**: Select the sample \mathbf{x} most likely to be positive (*sometimes used in cases where positive samples are extremely rare / hard to come by*)

$$\mathbf{x}^* = \arg \max_{\mathbf{x}} P(Y = 1|\mathbf{x})$$

Approaches (cont'd)

- ▶ **Query-by-Committee:** use an ensemble of classifiers (e.g., a random forest). Select the sample that most classifiers (e.g., trees in the forest) disagree on.
- ▶ **Model change:** Select the sample that is expected to lead to the biggest change in the model.
 - ▶ Example: Logistic Regression (weight vector \mathbf{w})
 - ▶ For each candidate sample \mathbf{x} , retrain the classifier once with $y = 1$ and once with $y = 0$, obtaining two new weight vectors \mathbf{w}_1 and \mathbf{w}_0 .
 - ▶ Pick the sample that leads to the largest difference:

$$\mathbf{x}^* = \arg \max_{\mathbf{x}} P(Y = 1|\mathbf{x}) \cdot |\mathbf{w}_1 - \mathbf{w}| + P(Y = 0|\mathbf{x}) \cdot |\mathbf{w}_0 - \mathbf{w}|$$

- ▶ Very very expensive (just for candidate refinement)

Approaches (cont'd)

- ▶ **Density-based methods** use the above quality measures Q and enforce an exploration of **new** areas
 - ▶ **Alternative 1:** Cluster the most highly-ranked candidate samples (according to Q) and pick representatives from the different clusters
 - ▶ **Alternative 2:** Downgrade candidate samples that are close to already labeled samples (*density-weighted repulsion*)

$$\mathbf{x}^* = \arg \max_{\mathbf{x}} Q(\mathbf{x}) \cdot (p^+(\mathbf{x}) + \epsilon)^{-\gamma}$$

Active Relevance Filtering

1. Active Learning

2. Anomaly Detection

Local Outlier Factor

One-class SVMs

Anomaly Detection: Mission Statement

Goal: identify samples that do not conform to an expected pattern, or to other samples in the dataset²

Applications

- ▶ credit card fraud detection
- ▶ detecting tumours in imagery
- ▶ detecting technical component failure
- ▶ finding errors in text
- ▶ network intrusion detection

²Chandola, Banerjee, Kumar: Anomaly Detection: A Survey. ACM Computing Surveys, 2009.

Anomaly Detection: Types of Anomalies

1. **point anomalies:** individuals that are unusual (e.g., in high distance) to the flock
2. **contextual anomalies:** use contextual features (e.g., location) and behavioral features (e.g., the temperature). An anomaly occurs if the behavioral features are unusual *given the contextual ones*.

Note: can be reduced to point anomalies using context-specific models

3. **collective anomalies:** a **combination** of samples that is unusual (whilst the individual samples are not necessarily).

Example: ... http-web smtp-mail
buffer-overflow ssh ftp ...

Our focus here will be on
point anomalies.

Anomaly Detection: Characteristics

Learning Setups

- ▶ Usually, there are two labels: *normal* vs. *abnormal*
- ▶ Labeled training data can be really difficult to find!
- ▶ **supervised** techniques: Training data from both classes given (but often highly imbalanced)
- ▶ **semi-supervised** techniques: Training data only for the *normal* class
- ▶ **unsupervised** techniques: training data without labels (there may be anomalies, but we do not know where)

Can we use Absolute Distance
as an Anomaly Criterion?

Anomaly Detection: Methods

There is a plethora of anomaly detection methods³

- ▶ ... some using regular classifiers
- ▶ ... some using density-based modeling
- ▶ ... some using rule mining
- ▶ ...

We will look at two of the most prominent ones:

- ▶ a density-based method (“local outlier factor”)
- ▶ a classification-based method (“one-class SVMs”)

³Chandola, Banerjee, Kumar: Anomaly Detection: A Survey. ACM Computing Surveys, 2009.

1. Active Learning

2. Anomaly Detection

Local Outlier Factor

One-class SVMs

Local Outlier Factor (LOF)⁴

- ▶ **Idea:** A sample x is a point anomaly if the point density in its surrounding is lower than in its nearest neighbor's surroundings.
- ▶ **Anomaly Measure:** Measure the distance to x 's neighbors, measure the same distance for each neighbor, and compare.

Derivation

⁴Breunig et al.: LOF: Identifying Density-based Local Outliers. Proc. ACM SIGMOD, 2000.

LOF: Derivation

We define $N_k(x)$ to be the set of K nearest neighbors to x , and $dist_k(x)$ as the distance of x to its k th nearest neighbor. Then, we define a distance between x and y :

$$d_{reach}(x, y) := \max\{dist_k(y), d(x, y)\}$$

(basically, this is $d(x, y)$, with a little tweak to achieve more stable results). Then we define the local reachability **density** as:

$$lrd_k(x) := \left(\frac{1}{\#N_k(x)} \cdot \sum_{y \in N_k(x)} d_{reach}(x, y) \right)^{-1}$$

We compute the local outlier factor by comparing x ' density with the one of its neighbors:

$$LOF_k(x) := \frac{1}{\#N_k(x)} \cdot \sum_{y \in N_k(x)} \frac{lrd_k(y)}{lrd_k(x)}$$

LOF: Example⁵

⁵Source: de.wikipedia.org

LOF: Discussion

- ▶ rather expensive: $O(n^2)$
(*speed-up by approximate NN search possible*)
- ▶ Speed-up using **sampling techniques**: determine LOF based on subsample, then when candidates have been identified, on larger sample
- ▶ **Benefit**: no prior assumptions regarding distribution of data

1. Active Learning

2. Anomaly Detection

Local Outlier Factor

One-class SVMs

Remember SVMs?

- ▶ a binary classifier that separates classes by a maximum margin hyperplane \mathbf{w}, b
- ▶ slack variables ξ_1, \dots, ξ_n that allow some training errors
- ▶ kernel trick to introduce non-linearity: map samples x_i to high-dimensional space $\phi(x_i)$

One-class SVMs

- ▶ same idea: find a hyperplane that separates “normal” samples from “abnormal” ones
- ▶ an unsupervised method: Our samples x_1, \dots, x_n may contain anomalies. We introduce slack variables to take them into account.

⁶Arcolano, Rudoy: One-Class Support Vector Machines: Methods and Applications. Project Presentation, Harvard University, 2008.

One-Class SVMs

Tradeoff between two Goals

- ▶ shift hyperplane as far away from the origin as possible
- ▶ at the same time, minimize number of “errors”

Quadratic Program

$$\min_{\mathbf{w}, \xi, \rho} \frac{1}{2} \cdot \|\mathbf{w}\|^2 + \frac{1}{\nu \cdot m} \cdot \sum_i (\xi_i - \rho)$$

subject to

$$\xi_i \geq 0 \quad \text{and} \quad \langle r, \phi(\mathbf{x}_i) \rangle \geq \rho - \xi_i \quad \forall i$$

- ▶ The parameter ν represents an upper bound on the fraction of training samples misclassified.
- ▶ For $\nu \rightarrow 0$, we obtain a “hard margin” problem.

One-Class SVMs: Example

One-Class SVMs: Remarks

- ▶ Applicable in high-dimensional settings where density estimation becomes tricky
- ▶ Key step: Kernel engineering (often: ad-hoc choice)
- ▶ Scalability to very large datasets tricky (usually, < 5000 samples for non-linear kernels)
